Abstract. The first China-Brazil Earth Resources Satellite (CBERS-1) was launched in 1999 and in 2003 was substituted by CBERS-2. CBERS-1 and CBERS-2 have the same specifications and carry three sensors: WFI, CCD and IR-MSS. The performance of these sensors can be evaluated through PSF measurement that enables an objective assessment of the spatial resolution. This paper describes an approach to estimate the spatial resolution of the CBERS-1 CCD camera using two images: an image captured by CBERS-1 satellite and an image of the same scene of higher resolution captured by SPOT-4 satellite. The method is iterative and the goal is to find the low-pass band filter parameter that minimizes the Root Mean Square (RMS) difference between the CBERS-1 image and the filtered SPOT-4 one. This technique is applied to spatial resolution estimation in across-track direction using an image of Lake Pontchartrain Causeway in Louisiana (United States), and, in along-track direction using an image of Rio-Niteroi Bridge in Rio de Janeiro (Brazil).

Keywords: CBERS-1 satellite, SPOT-4 satellite, CCD camera, spatial resolution, point spread function, estimation, modelling, simulation, measurement.

1. Introduction

In the last two decades China and Brazil have jointly developed through a cooperative program, the CBERS satellite (China-Brazil Earth Resources Satellite). The CBERS-1 and CBERS-2 satellites were launched on October 14, 1999 and October 21, 2003, respectively by the Chinese launcher Long-March 4B, from the Tayuan Launch Center, in the Popular Republic of China. The main objective of CBERS mission is to obtain global, regional, and local images of the Earth in four different wavelengths of the electromagnetic spectrum (spectral bands), ranging from visible to infrared light.

The CBERS-1 payload consists of three instruments called: CCD (Charge Coupled Device) camera, IR-MSS (Infrared MSS) and WFI (Wide Field Imager), which can capture optical observation of the Earth surface and transmit remotely sensed data to ground receiving stations.

During the acquisition process, the imaging system causes image degradations due to the cumulative effects of the instrumental optics (diffraction, aberrations, focusing error) and image motion induced by the satellite movement (Leger et al. 2002). Typically, the degradation can be modeled by linear system characterized by its Point Spread Function (PSF) or by its Modulation Transfer Function (MTF) in the frequency domain.

According to the literature, the PSF can be approximated by a Gaussian function (Luxen and Forster, 2002). Hence, in this work the PSF is modeled as two one-dimensional Gaussian functions: one relative to the along-track direction and the second one to the across-track direction.

The point spread function (PSF) of a given image acquisition system measure how the optical system spreads the image of a point, and it enables an objective assessment of the imaging system spatial resolution parameter. In remote sensing, the spatial resolution parameter is known as EIFOV and enables a comparison between different sensors. When the
PSF is approximated by a Gaussian function with standard deviation $\sigma$, the EIFOV is $2.66\sigma$ (Slater, 1980; Banon and Santos, 1993).

In this work, our goal is to estimate the spatial resolution using images from different sensors. SPOT-4 images have been chosen as a reference because they have slightly better resolution than the CBERS-1 images (Bensebaa, et al, 2004b), they have the same sampling rate. Furthermore, SPOT-4 EIFOVs are known and are used in CBERS-1 EIFOVs estimation. The method is iterative and consists of finding the low-pass band filter parameter that minimizes the Root Mean Square (RMS) difference between the CBERS-1 image and the filtered SPOT-4 one. This technique is applied to spatial resolution estimation in across-track direction using image of Lake Pontchartrain Causeway in Louisiana (United States), and, in along-track direction using image of Rio-Niteroi Bridge in Rio de Janeiro (Brazil).

2. CBERS-1 overview

The CBERS-1 satellite carries on-board a multisensor payload with different spatial resolution called: WFI (Wide Field Imager), IRMSS (Infrared MSS) and CCD (Charge Coupled Device) camera. The high-resolution CCD Camera has 4 spectral bands from visible light to near infrared and one panchromatic band (Table 1). It acquires the earth ground scenes by pushbroom scanning, on 778 km sun-synchronous orbit and provides images of 113 km wide strips with sampling rate of 20 meters at nadir Dayao et al. (2001).

</tbody>
</table>

The signal acquisition system operates in two channels called CCD1 and CCD2. The first one generates images corresponding to B2, B3 and B4 while the second generates images corresponding to the bands B1, B3 and B5. In each channel (channel C1 and channel C2), three CCD chips per band were combined to generate about 6000 pixels per row.

3. Point spread function (PSF) estimation methodology

The PSF estimation is a general tool for assessment of the imaging system performance. Basically, there exist three ways to determine the PSF. The first one uses images targets that must have well-defined shape and size as airport runway, bridges, etc or artificial target. The second method utilizes images acquired by higher resolution sensor, which are low-pass filtered and compared with the image under study (see Banon (1990) for a simulation study). Finally, the third one uses the system design specifications and the system analytic model (Fonseca, 1987; Fonseca and Mascarenhas, 1987).

The first two approaches have the advantage of estimating the imaging system PSF by using in-flight images. Previous works dealing with this problem have obtained satisfactory results using the first approach. Storey (2001) has used this methodology to measure the Landsat-TM on-orbit spatial response using ground target such as bridges. Choi and Helder (2001) have used as targets airport runway and a tarp placed on the ground for on-orbit MTF measurement of IKONOS satellite sensor. Bensebaa et al. (2004b) have used bridges images
to estimate the spatial resolution of CBERS-1 imaging system. The spatial resolution estimation used in this work is based on the second approach.

3.1 Target selection

The image selection was made based on separability properties. In order to make profit of the simplicity of working with 1D data, we chose images of along-track and across-track bridges, which are typically 1D, target. The Rio-Niteroi Bridge over Guanabara Bay (Figure 1 and Figure 3) was chosen as 1D target to estimate the spatial resolution in the along-track direction. This bridge is 13.29-km long with only one deck and its width is 26.6 meters. On the other side, the Causeway Bridge over the Lake Pontchartrain (Figure 2 and Figure 4) was used as 1D target to estimate the spatial resolution in across-track direction. The target is a 38.62-km long double deck bridge where each deck is 10.0 meters width and the gap is 24.4 meters width. The two decks of the bridge were constructed at different times (1956 and 1969) and exhibit slightly different reflectance. In addition, the water background is reasonably uniform.

3.2 Data preparation

The Rio-Niteroi bridge and Lake Pontchartrain Causeway bridge images were acquired by CBERS-1 CCD sensor on December 02, 2001 and October 06, 2002, respectively. The same scenes were acquired by SPOT-4 CCD on November 28, 2001 for Rio-Niteroi Bridge and on November 25, 2002 for Lake Pontchartrain Causeway Bridge.

The CBERS-1 raw data images present a striping effect. Odd columns are brighter than even columns. This is due to the non-uniform detector gains, since each detector is responsible for one column in the images. The processing procedure to remove the stripping effect has been described in (Bensebaa, et al. 2004a). Figure 5 and Figure 7 shows destriped images of Band2 captured by CBERS-1 satellite CCD while Figure 6 and Figure 8 shows images of Band2 captured by SPOT-4 satellite CCD.

3.3 Image registration

As the scenes images of Rio-Niteroi bridge and Causeway bridge were captured by different sensors, we have applied the registration algorithm developed by (Fedorov, et al, 2002). The SPOT-4 images were used as reference. Figures 9 and Figures 10 show the results of this processing.

Fig. 8 Band2 of Causeway bridge original image captured by SPOT 4 CCD.
3.4 Point spread function modelling

The overall on-orbit PSF is the convolution of each sub-system PSF: optic, detector, electronic, etc. In this work the point spread function is modeled as a 2D separable Gaussian function that is,

\[ h(x_1, x_2) = h_{\sigma_1}(x_1) h_{\sigma_2}(x_2), \]

where

\[ h_{\sigma}(x) = \frac{1}{\sqrt{2\pi\sigma}} e^{-\frac{x^2}{2\sigma^2}}. \]

In this work, the employed method for the CBERS-1 EIFOV estimation is based on the degradation of a SPOT-4 image. It assumes that the CBERS-1 and SPOT-4 image are registered and that the SPOT EIFOV of each band is known. Let \( f \) be the original scene and let \( h_s \) be the SPOT-4 imaging system PSF. Then the original SPOT-4 image is given by:

\[ g_s = h_s * f. \]

Let \( h_d \) be the degradation filter PSF. Then the SPOT-4 degraded image is given by:

\[ g_d = h_d * g_s = h_d * (h_l * f) = (h_d * h_l) * f. \]

Finally, let \( h_c \) the CBERS-1 imaging system PSF. Then, the CBERS-1 image is given by:

\[ g_c = h_c * f. \]
To find the PSF of CBERS-1 imaging system $h_c$, we minimize the difference between the CBERS-1 image $g_c$ and the SPOT-4 degraded image $g_d$ by adjusting $h_d$. At the minimum, $g_d \approx g_c$ and $h_c * h_i$ is our estimation for $h_c$. The figure 11 shows the block diagram of low-resolution image simulation.

![Fig.11 block diagram of low-resolution image simulation](image)

For the along-track and across-track spatial resolution estimation, a three-step approach was used. The first step consists of estimating a gain parameter for the radiometric adjust between CBERS-1 image and SPOT-4 image. The second step consists of finding an offset parameter that describes the residual registration error between both images. In the last step, the standard deviation parameter of degradation filter is estimated. This one is used to compute the EIFOV CBERS-1. In all steps the root-mean-square minimization is used. Details of the proposed method are presented below.

Let $g_c$ be one column (respectively one line) of the along-track (respectively across-track) bridge CBERS-1 image and $g_s$ be one column (respectively one line) of the along-track (respectively across-track) bridge SPOT-4 image.

Let denote by $g_{\mu,\sigma}$ be the degraded SPOT-4 column (respectively one line) that is:

$$g_{\mu,\sigma} = h_{\mu,\sigma} * g_s,$$

where $h_{\mu,\sigma}(x)=h_c(x-\mu)$.

**Step 1: Radiometric Adjust**

In this step, the radiometric adjust is based on the estimation of a gain parameter $a$ that allows to minimize the radiometry difference between the CBERS-1 column (respectively line) and the SPOT-4 column (respectively line).

Hence, given an a priori value $\sigma_0$ we look for the parameter $a$ which minimizes

$$\sum((ag_c + b) - g_{\mu,\sigma_0})^2,$$
where $b = m - a \cdot m_c$ (the initial value for $a$ in the minimization is $s/s_c$), $m_c$ and $s_c$ are the mean and standard deviation of $g_c$, and $m$ and $s$ are the mean and standard deviation of $g_s$.

**Step 2: Offset Adjust**

In this step $a$ and $b$ being the parameters found at step 1, we look for $\mu$ that minimizes

$$\sum \left( (ag_c + b) - g_{\mu,\sigma} \right)^2$$

**Step 3: EIFOV Estimation**

In this step $a$, $b$ and $\mu$ being the parameters found in the previous steps we look for $\sigma$ that minimizes

$$\sum \left( (ag_c + b) - g_{\mu,\sigma} \right)^2$$

The along-track (respectively across-track) EIFOV estimation of CBERS-1 imaging system is given by:

$$\text{EIFOV}_c = 2.66 \left( \text{EIFOV}_c \right)^2 + \sigma^2)^{1/2}$$

where EIFOVs is the along-track (respectively across-track) spatial resolution of SPOT-4 imaging system.

The final estimated value of the imaging system $\text{EIFOV}_c$ is the mean value of the $\text{EIFOV}_c$ obtained at each column (respectively each line).

In the three steps, the parameters have been obtained by nonlinear programming (Himmelblau, 1972).

4. Results

Table 2 and Table 3 present the EIFOV values of SPOT-4 imaging system used in this work. The results of the estimated parameters of CBERS-1 CCD imaging system are presented in Table 4 and Table 5.

| Bands | $\sigma_1$ |(EIFOV) $|_{1}$ | Bands | $\sigma_2$ |(EIFOV) $|_{2}$ |
|-------|------------|---------------|-------|------------|---------------|
| B2    | 10.56      | 28            | B2    | 10         | 27            |
| B3    | 11.26      | 30            | B3    | 10.7       | 29            |
| B4    | 11.63      | 31            | B4    | 12.6       | 34            |

| Bands | $\sigma_1$ |(EIFOV) $|_{1}$ | Bands | $\sigma_2$ |(EIFOV) $|_{2}$ |
|-------|------------|---------------|-------|------------|---------------|
| B2    | 12.74      | 34            | B2    | 24.34      | 65            |
| B3    | 13.8       | 37            | B3    | 24.1       | 64            |
| B4    | 20.3       | 54            | B4    | 28.75      | 77            |

| Bands | $\sigma_1$ |(EIFOV) $|_{1}$ | Bands | $\sigma_2$ |(EIFOV) $|_{2}$ |
|-------|------------|---------------|-------|------------|---------------|
| B2    | 12.74      | 34            | B2    | 24.34      | 65            |
| B3    | 13.8       | 37            | B3    | 24.1       | 64            |
| B4    | 20.3       | 54            | B4    | 28.75      | 77            |
5. Conclusion

An algorithm for the spatial resolution estimation of CBERS-1 CCD imaging system was presented. The proposed algorithm consisted of simulating a low resolution CBERS-1 image from a higher resolution SPOT-4 image. Our results confirm EIFOV’s values obtained in the previous work (Bensebaa et al, 2004a, b). In along-track direction the imaging system spatial resolution is in specifications for all bands except band 4. In across-track direction the imaging system spatial resolution is out of the specifications for all bands.
